

EMA Crossover Scalper

9/21 EMA starting model + pullback confirmation + EA rules

Educational notice: No strategy, EA, indicator, or candlestick pattern guarantees profit. Binary/short-expiry decisions are especially sensitive to timing, spread and execution. This material is a chart-reading and automation framework, not a guarantee of next-candle direction.

1. Strategy Identity

Example starting configuration: 9 EMA and 21 EMA on M5. Use higher-timeframe structure to avoid trading every crossover.

Core idea

- Fast EMA above slow EMA = bullish momentum candidate.
- Fast EMA below slow EMA = bearish momentum candidate.
- The crossover is a filter; the candlestick and market context provide the trigger.

2. Long A-to-Z

9 EMA crosses above 21 EMA or remains aligned bullish → price pulls back to EMA zone → bullish engulfing/rejection candle closes → entry → SL below pullback swing → TP 1.5R–2R or resistance.

3. Short A-to-Z

9 EMA crosses below 21 EMA or remains aligned bearish → price pulls back to EMA zone → bearish engulfing/rejection candle closes → entry → SL above pullback swing → TP 1.5R–2R or support.

4. Bad-Crossover Filter

Skip when both EMAs are flat, repeatedly crossing, or price is trapped in a narrow range. Prefer clean EMA separation plus directional structure.

5. Binary-Style Candle Timing

CALL-style: bullish EMA alignment + pullback + bullish confirmation close.

PUT-style: bearish EMA alignment + pullback + bearish confirmation close.

Do not treat a single candle as certainty for the next candle.

6. EA Architecture

Signal

- Process completed candles only.
- Calculate fast/slow EMA.
- Detect alignment/crossover and pullback.
- Require candle confirmation.

Execution & safety

- Risk-based sizing.
- Structure-based SL.
- Fixed-R or level-based TP.
- Max trades/day.
- Daily drawdown lock.
- Spread/slippage limits.
- Unique magic number and trade logging.

7. Optimization

Test EMA pairs and sessions separately. Use out-of-sample testing and robustness checks rather than selecting the combination with the highest historical profit.

Risk framework

- Risk 0.25%–1% per trade while testing; use a hard daily loss limit.
- Never use martingale or increase size to recover a loss.
- Define SL from market invalidation, not emotion; calculate position size from SL distance.
- Track expectancy, drawdown, profit factor, average R and consecutive losses—not only win rate.
- Backtest, forward-test on demo, then use small live risk.
